Common questions about building software using AI

Describe a project where you applied AI technologies (e.g., LLMs, AI agents) to solve a real-world problem.

- We can use AI technologies to understand data behavior and know what it is going to happen next.
- We can use AI technologies to find some pattern inside the data we are using and we could get from it, what we are specifically looking for.

What was your role, what tools or frameworks did you use, and how did you ensure the solution delivered measurable value to the end user?

We could ensure the solution delivered confirming the next assumptions:

- We reviewed the software development several times before it could be delivered.
- We made corrections on every code or software review.
- We created and shared documentation about the corrections we made before and communicated this in a technical and non-technical language.
- We made a presentation and show all the main features so that the end user know how to use them more properly.
